Rooms Containing Fuel-Burning Appliances - Code Compliance Brief

Overview:

The intent of this brief is to provide code-related information about rooms containing fuel-burning appliances to help ensure that the measure will be accepted as being in compliance with the code. Providing notes for codes officials on how to plan review and conduct field inspections can help builders or remodelers with proposed designs and provide jurisdictional officials with information for acceptance. Providing the same information to all interested parties (e.g., code officials, builders, designers, etc.) is expected to result in increased compliance and fewer innovations being questioned at the time of plan review and/or field inspection.

As houses are being built "tighter" to meet stricter air leakage requirements (e.g., climate zones 1-3 at 5 ACH/50 [air changes per hour at 50 Pa]) and climate zones 3-8 at 3 ACH/50 in the 2015 International Energy Conservation Code (IECC) and International Residential Code (IRC), concern has risen for installing natural-draft gas appliances\(^1\) (vented\(^2\) or direct-vented appliances\(^3\)) in these tighter homes without dealing with issues related to back-drafting due to possible increased negative pressure near the combustion\(^4\) appliance and drawing carbon monoxide into the building. For example, this scenario could potentially occur in a somewhat tight home tested at 900 cfm (cubic feet per minute) (e.g., a 2000-square foot home with 9-foot ceiling heights = 18,000 cubic feet/volume) by turning on one exhaust fan (e.g., 300 cfm), which could depressurize the home to the point that no natural-draft gas appliance could safely draft under these conditions\(^5\).

In an attempt to deal with these combustion issues, an entirely new section in the 2015 IECC/IRC regarding fuel-burning appliances\(^6\) basically requires the appliance to be isolated from the building thermal envelope, located either outside or within a separate room if the fuel-burning appliance is supplied by open combustion air ducts. The room must be insulated and sealed off from the rest of the conditioned space. Furthermore, a NEW Appendix ‘RA’ has been added providing for a Code Official's option to require a Combustion Appliance Zone (CAZ) test to verify "manufacturer's operational parameters" for venting byproducts of combustion in a "tight" <5 ACH/50 (air changes per hour) home.

This brief provides an overview of the requirements and further details of approving the actual "room," based on equipment choices and location of installed equipment, approving the "open combustion air ducts" as to the installation, insulation and sealing of the ducts, and any other ducts or water lines in the "room."

---

1. *Appliance* is defined in the 2015 IECC/IRC as any apparatus or device that uses a fuel or raw material to produce light, heat, power, refrigeration, or air conditioning.
2. *Appliance, vented* is defined as an appliance designed and installed in such a manner that all of the products of combustion are conveyed directly from the appliance to the outside atmosphere through an approved chimney or vent system.
3. *Direct-vent appliance* is defined as an appliance that is constructed and installed so that all air for combustion is derived directly from the outside atmosphere and all flue gases are discharged directly to the outside atmosphere.
4. *Combustion* is defined as in the context of the code referring to rapid oxidation of fuel accompanied by the production of heat or heat and light.
6. *Building Thermal Envelope* is defined as the basement walls, exterior walls, floor, roof, and any other building elements that enclose conditioned space or provide a boundary between conditioned space and exempt or unconditioned space.

Plan Review:

Per the 2015 IECC/IRC, Section R103.3/R106.3, Examination of Documents. The code official/building official must examine, or cause to be examined, construction documents for code compliance.

This section lists the applicable code requirements followed by details helpful for plan review regarding the provisions to meet the requirement for "rooms containing fuel-burning appliances." The first bullet item below is the code requirement itself. The remaining bullets are items to meet the requirement.

*
FAQ'S: Where the air infiltration rate of a structure is known, the minimum required volume shall be determined per the equations cited in this section. Door leading into the "room" is an insulated door, is weather-stripped with a threshold, and remains closed. The door should be fully gasketed and any water lines and ducts in the room insulated according to Section R403 (IECC)/Section N1103 (IRC) regarding Systems. The combustion air duct(s) should be insulated to a minimum of R-8 where it passes through conditioned space.

Exceptions:

1. Direct vent appliances with both intake and exhaust pipes installed continuous to the outside.

2. Fireplaces and stoves complying with Section R402.4.2 (IECC)/N1102.4.2 (IRC) and Section R1006 (IRC).

— Construction Documentation. Review the construction documents to identify the equipment, system controllers, design, and ventilation choices for combustion air or supply air to equipment. If combustion air vented appliances will be installed, confirm the provisions of the code provided in this brief.

— Insulation. Review the construction documents and confirm that the insulation R-values specified meet or exceed the minimum insulation requirements for the "room."

a The basement wall R-values are the minimum insulation requirements for the "room." The first R-value is continuous insulation with no thermal breaks; the second R-value is cavity insulation between studs or framing members.

Code Compliant Minimum Insulation Levels for the "Room"

Note: The actual code provision does not explicitly address requirements for any windows, skylights, slab-on-grade, or the door leading into the "room." If the "room" has any windows or skylights or is located as part of the building thermal envelope where one or more of the walls are exterior walls on a slab-on-grade foundation, then those components should meet the minimum insulation and fenestration values per Table R402.1.2/N1102.1.2. Also, because the "room" is to be isolated from the rest of the home, it should have an exterior type door (i.e., insulated door), not an interior door (i.e., hollow core) and should not have any grills or openings in it.

<td>5/13</td>
<td>5/13</td>
<td>15/19</td>
<td>15/19</td>
<td>15/19</td>
</tr>
</tbody>
</table>

a The first R-value is continuous insulation with no thermal breaks; the second R-value is cavity insulation between studs or framing members. Either one will meet the minimum insulation requirements for the "room."

— Air Sealing/Air Leakage Control. The same air sealing provisions for the building thermal envelope apply to the "room."

— 2015 IRC/IECC, Air Barrier and Insulation Installation Table R402.4.1.1/N1102.4.1.1

- Continuous air barrier — Confirm that construction documents specify a continuous air barrier for the building components that define the "room" to include the ceiling, walls, and floor.
