2021 IECC Climate Zone 4C: Vented Attic, Interior Double Wall, Interior Insulated Basement

Roofing			
Roofing underlayment		\sim	
Roof sheathing		\sim	
Raised-heel roof truss provides increased depth ofroof insulation at perimeter			
Insulation baffle prevents wind blowing		EFAT	
Water-protection membrane (ice-dam protection where required)			
Continuous soffit vent			 Polyethylene air barrier and vapor barrier (class I vapor retarder)
R-60 insulation: cellulose, fiberglass, — or mineral wool Wood or fiber cement siding — ,			 Ceiling gypsum board installed before wall gypsum board with room perimeters caulked with sealant to top plates
Furring or spacer strip			- Fire stop
Building paper, housewrap, or building wrap		$\blacksquare -$	1/2" gypsum board with latex paint
Plywood, OSB, gypsum,			(class III vapor retarder) - R-13 insulation: cellulose, fiberglass,
R-13 cavity insulation in 2x4 outer			mineral wool, or open-cell spray foam
wood framing: cellulose, fiberglass, mineral wool, or open-cell spray foam			 Polyethylene air barrier and vapor barrier (class I vapor retarder)
2x4 outer wood framing	R		 Polyethylene vapor barrier taped to vapor-permeable building wrap to
2X4 inner wood framing			form continuous air barrier
Minimum R-4 insulation in gap between outer wood framing and inner wood framing:			 Vapor-permeable building wrap taped to sub-floor
cellulose, fiberglass, mineral wool, or open-cell spray foam			- Sill gasket
Vapor-permeable building wrap		\square	- Foam filler
wrapped around floor assembly (class III vapor retarder)			- 1/2" gypsum board with latex paint
/	ال م تفر _{حا} د		(class III vapor retarder)
Sill plate installed over	4 _{L⊐} 28/∆		2X4 wood frame wall
sill gasket and air barrier Impermeable backfill	A		- R-13 insulation: cellulose, fiberglass, mineral wool, or open-cell spray foam
("clay cap")			R-5 rigid insulation with joints taped:
Sealant bead sealing	{		extruded polystyrene or foil-faced polyisocyanurate
rigid insulation to foundation wall			 Joint in rigid insulation to facilitate application of sealant
Free-draining backfill	A . A .	\square	 Sealant bead sealing rigid insulation to slab
Dampproofing			- Sill gasket
Concrete foundation wall	→ ⊿⊲		 Treated wood bottom plate
Course gravel			n la a la la a la
(no fines)			
Filter fabric			- 4" concrete slab
	Ī		— Polyethylene vapor barrier
Perforated drain pipe			R-10 rigid insulation; 2"
Capillary break overfooting (dampproofing			extruded polystyrene
or membrane)			b-slab stone layer (no fines)
Concrete footing		Rigid insulation as bond break	
	— Drain pipe through footing		

2021 IECC Climate Zone 4C: Vented Attic, Interior Double Wall, Interior Insulated Basement

• The function of the raised-heel roof truss is to control the temperature of the interior corner where the exterior wall meets the ceiling to control dust marking and mold. The minimum thermal resistance over the top of the wall assembly should match or exceed the thermal resistance of the wall assembly. Increasing the height of the raised heel can allow lower attic insulation levels by code. Per IECC 2021 Section R402.2.1, Ceilings with Attics, the ceiling insulation of this assembly can be R-49 rather than R-60 if the raised-heel roof truss is high enough to facilitate R-49 over the entire wall.

• A low-permeance roofing underlayment (less than 1 perm) is recommended for this roof type in this climate to reduce water diffusion through the underlayment to the sheathing.

• The ceiling gypsum board is installed prior to the wall gypsum board in order to accommodate a "filet" bead of sealant that seals the ceiling gypsum board to the top plates creating a continuous air control layer ("air barrier") across the entire ceiling including interior partition walls. The gypsum board is the air control layer. The polyethylene at the ceiling is the vapor control layer.

• The gap between the exterior wall and the interior wall needs to be fire-stopped where the wall assemblies intersect the attic assembly. The gap between the outer wall framing and the inner wall framing can be increased to accommodate more insulation.

• Depending on interpretation, this assembly may not meet the 2021 IRC prescriptive requirements for vapor control. However, the assembly meets the intent of the code by keeping the first condensing surface above condensing temperatures. The first condensing surface within this assembly is the interior surface of the polyethylene vapor barrier inside the wall. More than half of the insulation in the assembly is to the outside of this surface, which helps it stay above condensing temperatures. The insulation requirements in 2021 IRC Table R702.7(3).

• The rim joist is wrapped with a vapor-permeable building wrap to avoid installing a non-insulating vapor barrier on the exterior of the framing in a cold climate, as this could cause condensation. The rim joist building wrap should be overlapped and taped to the polyethylene vapor barrier to form a continuous air barrier.

• The typical sequence of construction to create this continuous air barrier requires building the inner wall portion of the double wall after the outer walls and roof system have been installed. Frame the inner walls on the floor and attach the polyethylene vapor barrier to the outside of the wall while it is still flat on the floor (before standing the wall up). By leaving enough extra polyethylene at the top, bottom, and sides of the wall, it can wrap around the ends of the wall to connect to the other air and vapor barriers by taping. It may be easier to install the polyethylene on the inside of the outer wall instead of the outside of the inner wall, but this arrangement may not control condensation, as there will be less insulation to the outside of the vapor barrier.

• The R-5 rigid insulation on the interior of the concrete foundation wall is required to control condensation within the interior frame wall as there is no interior vapor barrier on the interior of the frame wall – there is a Class III vapor "retarder" (semi-permeable latex paint). The reason that there is no interior vapor barrier on the interior of the frame wall is to permit drying to the interior. Additionally, the R-5 rigid insulation on the interior of the concrete foundation wall reduces the rate at which moisture contained in newly placed concrete moves to the interior.

• The vertical "short" strip of rigid insulation where the basement concrete slab intersects the exterior concrete basement wall has two lines of continuous sealant. The first seals the concrete slab edge to the interior surface of the vertical strip. The second seals the top back corner of the vertical strip to the concrete foundation wall. The two seals provide air control layer continuity between the concrete slab and the concrete wall to control radon and other soil gases.

• Horizontal insulation on the underside of the concrete floor slab is provided for comfort reasons and to control dust mites in carpets by reducing the relative humidity within the carpets.
